Four color theorem

On
Heawood-type
problem for maps
with tangencies.

Gleb Nenashev

History

Defenitions

Results

Case $\mathcal{A}_{1,g}$

Given any separation of a plane into connected regions, called a map, the regions can be colored using at most four colors so that no two adjacent regions have the same color.

In graph terminology: every planar graph is four-colorable.

This theorem was proved in 1976 by [Kenneth Appel](#) and [Wolfgang Haken](#).

Case $\mathcal{A}_{1,g}$

The minimum number of colors necessary to color all graphs drawn on an orientable surface of genus $g > 0$ is equal to

$$\left\lfloor \frac{7 + \sqrt{1 + 48g}}{2} \right\rfloor.$$

In 1890 [Percy John Heawood](#) conjectured and proved that this number of colors is enough.

In 1954 [Gerhard Ringel](#) constructed an infinite series of examples which confirm the accuracy of the estimate up to a constant.

In 1968 [Gerhard Ringel](#) and [Ted Youngs](#) solved the problem.

Results

Case $\mathcal{A}_{1,g}$

Let k be a nonnegative integer. We say that a graph is k -planar, if it can be drawn on the plane such that any edge intersects at most k other edges.

What is the minimum number of colors necessary to color all 1-planar graphs?

In 1965 Gerhard Ringel proved that this number is equal to 6 or 7.

In 1984 Oleg V. Borodin proved that this number is equal to 6.

Let k and g be nonnegative integers. Let us denote by $\mathcal{A}_{k,g}$ the class of all graphs without loops and multiple edges which can be drawn on a surface of genus g , such that any edge intersects not more than k other edges.

Let k and g be nonnegative integers. Let us denote by $\mathcal{B}_{k,g}$ the class of all maps on the surface of genus g such that any $k + 1$ regions have no common point.

Four color theorem is equivalent to that every map of $\mathcal{B}_{3,0}$ can be colored with four colors.

$\chi(G)$ — is the smallest number of colors needed to color the vertices of a graph G such that no two adjacent vertices have the same color.

$\chi(B)$ — is the smallest number of colors needed to color the regions of map B such that no two regions having a common point share the same color.

Let \mathcal{C} - a class of graphs (maps), we denote by $\chi(\mathcal{C})$ - the minimum number of colors that can be colored every graph (map) in the class \mathcal{C} .

The following inequality holds for $g > 0$

$$\chi(\mathcal{B}_{k,g}) \leq \frac{2k + 1 + \sqrt{4k^2 - 12k + 16gk + 1}}{2}.$$

Conjecture: The difference between the left and right parts are not greater than some constant c_k .

For $g \geq 0$

$$\chi(\mathcal{B}_{k,g}) \leq \chi(\mathcal{A}_{\lceil \frac{k-2}{2} \rceil \lfloor \frac{k-2}{2} \rfloor, g}).$$

Conjecture: We have the equality.

$$K_{25}, 25 = 9 + 16t$$

1. Cubic graph on $4t + 2$ vertices.
2. Bypass: it by turning in each black vertex clockwise, and in white counterclockwise. We obtain a cycle when we go along each edge twice (in both direction).
3. Dashed edges form a perfect matching.
4. We defined the orientation and numbers on the edges such that the sum of incoming numbers and outgoing are equal modulo $9 + 16t$.
5. All \pm number on the edges, and the difference between the numbers in the bypass before and after each dashed edge are different modulo $9 + 16t$.

The ribbon structure of our graph:

a: $(a+7)$ $a+2$ $(a-11)$ $a-6$ $(a-9)$ $a+4$ $a+22 \dots$

$$a + 7: \dots a + 7 + 6 \quad a + 7 + 20 \quad (a) \dots$$

Results

Case $\mathcal{A}_{1,g}$

The ribbon structure of our graph:

a : $(a+7)$ $a+2$ $(a-11)$ $a-6$ $(a-9)$ $a+4$ $a+22 \dots$

$a+7$: $\dots a+7+6$ $a+7+20$ $(a) \dots$

All faces are triangles and each of them has exactly one dashed edge.

We draw in two adjacent triangles (by dashed edge) the diagonal edge across the common dashed edge.

We get a complete graph if our auxiliary cubic graph satisfied those 5 conditions written above.

Thank you for your attention
